GOT A BUG IN AN  
ACS ROUTINE...

SMS/Debug is three tools that allow your installation to debug ACS routines, demystify SMS volume selection and reveal all of the DADSM return codes, not just the last one.

**ACS Routine Tracing:** Could you imagine COBOL or C++ with out a trace facility? SMS/Debug can display the logic flow for all four ACS Routines for a selected data set. This can be invaluable in trying to determine how this data set was assigned to that storage group.

**Volume Selection Tracing:** Trying to determine which volumes are in the primary, secondary and tertiary volume list is very difficult. SMS/Debug can display all of the volumes SMS considered for volume selection, list assignment and threshold values at the time of allocation, not hours later.

**DADSM Exit Tracing:** SMS only gives you the last DADSM return code but SMS/Debug can display all of the return codes including a description so it is much easier to determine why a volume was rejected for allocation.

To purchase SMS/Debug contact:
